RIGHT ELBOW MRI EXAMINATION (3 T):

Technique: Non-contrast and contrast-enhanced multiplanar, multisequence MRI examination was performed on a 3 Tesla MRI scanner.

Indication : Long-standing swelling, tenderness, and restriction of motion in the elbow in a patient diagnosed with rheumatoid arthritis.

Findings::

*Corticosubcortical irregularity, focal erosions, periarticular bone marrow edema, loss of articular cartilage integrity—more pronounced on the radial side—and multiple cystic resorptions—most prominent in the olecranon—are observed on the joint surfaces of the distal humerus, proximal radius, and ulna.

*Dense intra-articular effusion in the elbow joint and heterogeneous, prominent contrast enhancement that may be interpreted in favor of pannus are seen.

*Mild lateral epicondylitis findings are visualized.

*Mild triceps tenosynovitis is present.

*Distal insertion levels of the biceps brachii and brachialis tendons are intact.

*Edema and band-like fluid are also observed around the ulnar nerve at the level of the elbow joint.

*A single lymph node measuring 6.6x4.1x6.9 mm with an obscured fatty hilum is observed subcutaneously on

the ulnar side of the distal arm (inflammatory ?).
